Summary/Abstract

⁶ aurel is an open-source Python package designed to automatically calculate *relativistic*
⁷ quantities. It uses an efficient, flexible and user-friendly caching and dependency-tracking
⁸ system, ideal for managing the highly nonlinear nature of general relativity. The package
⁹ supports both symbolic and numerical calculations. The symbolic part extends SymPy with
¹⁰ additional tensorial calculations. The numerical part computes a wide range of tensorial
¹¹ quantities, such as curvature, matter kinematics and much more, directly from any spacetime
¹² and matter data arrays using finite-difference methods. Inputs can be either generated from
¹³ analytical expressions or imported from numerical relativity simulations. For users of Einstein
¹⁴ Toolkit, aurel also provides utilities to load 3D data generated with Carpet. Given the
¹⁵ increasing use of numerical relativity, aurel offers a timely post-processing tool to support the
¹⁶ popularisation of this field.

Statement of need

¹⁸ General relativity describes matter as moving according to how distances shrink or expand;
¹⁹ likewise, the intervals of time and space evolve depending on the distribution of matter.
²⁰ Handling this dynamic “mesh” of distances and times requires elaborate tensor algebra that,
²¹ in some cases, can only be managed with symbolic or numerical tools. Naturally, numerical
²² relativity has become an essential tool in modern astrophysics, cosmology, and gravitational
²³ physics, most notably in the modelling of gravitational-wave signals.

²⁴ While established computational frameworks focus on solving and evolving Einstein’s field
²⁵ equations with specific key diagnostics, they leave calculations of the remaining analysis to the
²⁶ discretion of the researchers. Newcomers to the field then face a substantial overhead until
²⁷ they develop their own personal post-processing codes. Established researchers also face the
²⁸ tedious task of handling intermediary variables and indices when calculating new quantities.
²⁹ The field then suffers from this error-prone, time-consuming process and would benefit from
³⁰ an accessible, open-source, standardised framework to automate these steps.

³¹ Therefore, we present aurel, an open-source Python package designed to streamline relativistic
³² calculations. It is hosted on [GitHub](#) and is available on [PyPI](#). The documentation is available
³³ through [GitHub Pages](#).

Features

³⁵ aurel provides an intuitive interface for the automatic calculation of general relativistic
³⁶ quantities, either symbolically (with AurelCoreSymbolic, built on SymPy ([Meurer et al., 2017](#)))
³⁷ or numerically (with AurelCore, which heavily utilises numpy.einsum ([Harris et al., 2020](#)) for
³⁸ efficient operations on array data structures).

39 Both require base quantities such as the spacetime coordinates or the parameters of the
40 Cartesian numerical grid, as well as the spacetime and matter distributions (the Minkowski
41 vacuum is otherwise assumed). These inputs can either come from analytical expressions,
42 with a couple of built-in solutions available, or from output data from any numerical relativity
43 simulations.

44 Specifically, for simulations run with Carpet in the Einstein Toolkit, the reading module
45 provides helper functions to load data in that specific format. These can read the parameter
46 file, create summarising files of the iterations and data variables available. Then the
47 `read_data` function can handle data separated into different simulation restarts, join different
48 multiprocessing chunks, and read different refinement levels. Since the raw data can sometimes
49 take a long time to open, `read_data` can also split the data per iteration, instead of per
50 variable, for quicker access in future reads. Additionally, `read_data` also has the capacity to
51 read in data directly from checkpoint files instead.

52 Then, once input data is provided, users can directly request a wide range of relativistic
53 quantities, including: spacetime; matter (Eulerian, Lagrangian, or conserved); BSSNOK;
54 constraints; fluid covariant kinematics; null ray expansion; 3- and 4-dimensional curvature;
55 gravito-electromagnetism; Weyl scalars and invariants (including gravitational waves). To see
56 a full list of available quantities, see: [descriptions](#). Tools are also provided for spatial and
57 spacetime covariant derivatives and Lie derivatives. All spatial derivatives are computed by the
58 `FiniteDifference` class that provides 2nd, 4th, 6th and 8th order schemes, using periodic,
59 symmetric or one-sided boundary conditions.

60 Automatic Computational Pathway

61 The `aurel` automatic process composes a computational pathway at runtime to evaluate
62 the requested quantities. This is implemented through a lazy-evaluation memoised property
63 pattern, where each quantity is defined as a method of the core class that may depend on
64 other quantities.

65 Users request quantities via a dictionary-style access, e.g. `rel["s_RicciS"]`, which triggers the
66 lazy memoised check to see if this is already cached. If yes, then the result is directly returned.
67 If not, then the corresponding method is called, which recursively triggers the calculation of
68 dependencies (e.g. `rel["s_Ricci_down3"]`). This continues until the requested quantities can
69 be calculated and so returned.

70 To avoid redundant computations, each result is cached, which builds up a cache memory that
71 needs to be efficiently managed. So, inspired by Python's garbage collection, `aurel` uses an
72 intelligent eviction policy that tracks memory footprint, evaluation counts, and last-access
73 times. When the configurable thresholds are exceeded, the older and heavier cached quantities
74 are removed, while safeguarding protected base quantities. Throughout this process, `aurel`
75 keeps the user informed on progress by providing verbose updates on the computation and
76 caching workflow.

77 Time dependence

78 All calculations within the `AurelCore` class are evaluated at a single fixed time, corresponding
79 to one slice in time, so that individual time steps can be treated independently. For multiple
80 time steps, an `AurelCore` object needs to be created and the requested quantities collected for
81 each.

82 To streamline this process, `aurel` provides the `over_time` function to do exactly this, and
83 also compute summary statistics over the grid domain (e.g., max/min) at each time step. By
84 design, it is easily extensible, so `over_time` also accepts custom functions of new relativistic
85 quantities and summary statistics. This makes `aurel` versatile, supporting an infinite number
86 of ways to view a problem and develop diagnostic tools.

87 Related packages

88 EBWeyl ([Munoz & Bruni, 2023](#)) was a precursor to aurel as it provided calculations of
89 gravito-electromagnetic contributions from base spacetime and matter quantities. aurel has
90 a completely different structure (relying on the automatic dependency resolution), provides
91 calculations of many more terms, over time, and has entirely new features: symbolic calculations,
92 reading Einstein Toolkit data, and built-in solutions. These capabilities, therefore, overlap
93 with many other codes; below, we list only Python packages.

94 aurel provides symbolic calculations, so may overlap with other general relativity symbolic
95 packages, see: GraviPy ([Czaja, n.d.](#)), SageManifolds ([Gourgoulhon et al., 2015](#)), EinsteinPy
96 ([Bapat et al., 2020](#)), Pytearcat ([Martín & Sureda, 2022](#)), and OGRePy ([Shoshany, 2025](#)).

97 aurel can work with data from any origin, whether analytically generated or from a numerical
98 relativity simulation; they just need to be passed as numpy arrays. But aurel also provides
99 tools to read 3D data from Carpet Einstein Toolkit simulations ([Löffler & others, 2012](#);
100 [Rizzo et al., 2025](#)). Therefore, there is also an overlap with: PostCactus ([Kastaun, n.d.](#)),
101 kuibit ([Bozzola, 2021](#)), scidata ([Radice, n.d.](#)), and mayawaves ([Ferguson et al., 2025](#)).

102 Then, several notable Python packages for general relativity focus on different aspects beyond
103 the current targets of aurel: - code generation: NRPy ([Ruchlin et al., 2018](#)) - evolution
104 codes: COFFEE ([Doulis et al., 2019](#)) and Engrenage ([Clough & Aurrekoetxea, n.d.](#)) - geodesic
105 and raytracing: PyHole ([Wittig & Grover, 2017](#)), EinsteinPy ([Bapat et al., 2020](#)), GRE0Py
106 ([Hackstein & Hackmann, 2025](#)), PyGR0 ([Della Monica, 2025](#)) - marginaly trapped outer surfaces:
107 distorted-motsfinder ([Pook-Kolb et al., 2019](#))

108 Acknowledgements

109 We thank Nat Kemp for being one of the first testers of aurel. We thank Ian Hawke for
110 support and suggestions.
